# Microwave synthesis and photoluminescent properties of $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$ ( $\text{Ln} = \text{Er}, \text{Ho}, \text{Tm}$ )

© Higher Education Press and Springer-Verlag 2007

**Abstract**  $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$  ( $\text{Ln} = \text{Er}, \text{Ho}, \text{Tm}$ ) phosphors were synthesized with the microwave radiation method for the first time. The luminescent properties of the samples were investigated and the up-conversion luminescence of  $\text{Er}^{3+}$ ,  $\text{Ho}^{3+}$  and  $\text{Tm}^{3+}$  doped  $\text{Sr}_2\text{CeO}_4$  phosphors was observed. The spectra indicate that the energy transfer takes place from the triplet excited state of MLCT (metal-to-ligand charge transfer) state for  $\text{Sr}_2\text{CeO}_4$  (sensitizer) to the rare earth ions (activator).

**Keywords**  $\text{Sr}_2\text{CeO}_4$ ,  $\text{Er}^{3+}$ ,  $\text{Ho}^{3+}$ ,  $\text{Tm}^{3+}$ , luminescence, up-conversion luminescence, microwave radiation

## 1 Introduction

In recent years, the research activities on the up-conversion about the doping of rare earth ions underwent a tremendous upsurge. Among them,  $\text{Er}^{3+}$ ,  $\text{Ho}^{3+}$  and  $\text{Tm}^{3+}$  ions are of particular interest due to their abundant energy level and fluorescence emissions in the regions of visible lights and near infrared rays [1]. In 1998, Danielson et al. [2] reported a novel blue luminescent material,  $\text{Sr}_2\text{CeO}_4$ , obtained by use of a combinatorial technique. This material was found to exhibit efficient blue-white luminescence under the excitation with ultraviolet (UV) lights, X-rays or cathode rays. Several researchers also investigated the detailed emission mechanism of this phosphor.  $\text{Sr}_2\text{CeO}_4$  is a phosphor with 100% active center concentration, so all  $\text{CeO}_6$  octahedra may be considered as luminescence centers and the quantum efficiency is very high. It owns a broad emission band, and may also act as a sensitizer to transfer the absorbed energy to the dopants (activator), such as the rare earth ions [3]. The rare earth-doped  $\text{Sr}_2\text{CeO}_4$  ( $\text{Sr}_2\text{CeO}_4:\text{Ln}^{3+}$ ;  $\text{Ln} = \text{Eu}^{3+}, \text{Sm}^{3+}$ ) was

investigated, and the characteristic emissions corresponding to doped rare earth ions affected by energy transfer were observed in literatures [4–8]. However, only one paper has been published concerning the doping of  $\text{Er}^{3+}$ ,  $\text{Ho}^{3+}$  and  $\text{Tm}^{3+}$  ions in  $\text{Sr}_2\text{CeO}_4$ . In that paper,  $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$  ( $\text{Ln} = \text{Er}, \text{Ho}, \text{Tm}$ ) phosphor particles were prepared by using an emulsion liquid membrane (ELM) system [9] and the energy transfer from  $\text{Ce}^{4+}$  to  $\text{Ln}^{3+}$  was investigated, but the effect of the concentration of dopant ions ( $\text{Ln}^{3+}$ ) on the emission of  $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$  was not discussed in detail, and the methods of preparing  $\text{Sr}_2\text{CeO}_4$  are complicated by demanding a very high calcination temperature.

The method of microwave irradiation, which shows the characteristic of the rapid and homogeneous heating rate [10] and the capability of producing luminescent materials with remarkably improved performance, has become one of the most distinctive methods in the synthesis of new materials. In this paper,  $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$  ( $\text{Ln} = \text{Er}, \text{Ho}, \text{Tm}$ ) phosphors were synthesized by the microwave irradiation method for the first time. The effect of the concentration of dopant ions ( $\text{Ln}^{3+}$ ) on the luminescence of  $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$  was investigated and the up-conversion luminescence of  $\text{Er}^{3+}$ ,  $\text{Ho}^{3+}$  and  $\text{Tm}^{3+}$  doped  $\text{Sr}_2\text{CeO}_4$  phosphors was observed.

## 2 Experimental

### 2.1 Materials and methods

The starting materials are:  $\text{SrCO}_3$ ,  $\text{CeO}_2$ ,  $\text{Er}_2\text{O}_3$ ,  $\text{Ho}_2\text{O}_3$  (all of 99.99% purity). The experimental setup used for microwave heating is an LGMG-501371 domestic microwave oven from the electronic limited company of Lejin Electronic Ltd. in Tianjin. Excitation and emission spectra were recorded at the room temperature with a Hitachi F-4500 spectrofluorometer from the Rily Company of Japan.

### 2.2 Synthesis of $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$ ( $\text{Ln} = \text{Er}, \text{Ho}, \text{Tm}$ )

Following  $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$  compounds can be prepared by using a mixture of Sr, Ln and Ce with a ratio of  $(2-x):x:1$ .

- (1)  $\text{Sr}_2\text{CeO}_4/x\text{Er}^{3+}$  ( $x = 0.01, 0.02, 0.04, 0.08$ )
- (2)  $\text{Sr}_2\text{CeO}_4/x\text{Ho}^{3+}$  ( $x = 0.01, 0.02, 0.05, 0.08, 0.10$ )
- (3)  $\text{Sr}_2\text{CeO}_4/x\text{Tm}^{3+}$  ( $x = 0.01, 0.02, 0.05, 0.08, 0.10$ )

In the microwave synthesis experiments, the  $\text{SrCO}_3$ ,  $\text{CeO}_2$ ,  $\text{Er}_2\text{O}_3$ ,  $\text{Ho}_2\text{O}_3$  and  $\text{Tm}_2\text{O}_3$  were weighed respectively, fully mixed and placed in a small crucible within a dual crucible system. The microwave irradiation was carried out with adjustable power and heating time in the presence of an appropriate amount of  $\text{MnO}_2$  as microwave absorbent. The obtained sample was taken out and cooled. In a preliminary study, the best reaction condition for the microwave synthesis of  $\text{Sr}_2\text{CeO}_4/\text{Ln}^{3+}$  was determined to be 560 w for 60 min. Thus, the power of the microwave oven was set up to 560 w and the heating time 60 min for the synthesis.

### 2.3 Spectra measurements

The emission and excitation spectra of the samples were recorded by using a Hitachi F-4500 spectrofluorometer. The controlling slit, excitation and emission rasters are all 2.5 nm.

## 3 Result and discussion

### 3.1 Luminescent properties of $\text{Sr}_2\text{CeO}_4/\text{Er}^{3+}$

Figure 1 shows the emission spectra of  $\text{Sr}_2\text{CeO}_4/x\text{Er}^{3+}$  when excited with  $\lambda = 283$  nm. As shown in Fig. 1, the emission spectra of  $\text{Sr}_2\text{CeO}_4/x\text{Er}^{3+}$  are composed of broadband peaks and line peaks. A broadband peak around 470 nm appears between 400 and 540 nm originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT (metal-to-ligand charge transfer). A number of line emission peaks are attached to the broadband peak originating from the  $4f \rightarrow 4f$  excited state of  $\text{Er}^{3+}$ , which could be assigned to  ${}^2\text{H}_{11/2} \rightarrow {}^4\text{I}_{15/2}$  (525 nm) and  ${}^4\text{S}_{3/2} \rightarrow {}^4\text{I}_{15/2}$  (548 nm) transitions, respectively. Among them, the highest peak is located at 548 nm. In addition, a splitting occurs at the line emission peaks of  $\text{Er}^{3+}$  ions due to the crystal field interaction, and the splitting extents of emission peaks are determined by the

**Fig. 1** Emission spectra of  $\text{Sr}_2\text{CeO}_4: x\text{Er}^{3+}$  ( $\lambda_{\text{ex}} = 283$  nm)  
1.  $x = 0.01$ ; 2.  $x = 0.02$ ; 3.  $x = 0.04$ ; 4.  $x = 0.08$

symmetry of the crystal field around the host materials [12,13].

$\text{Sr}_2\text{CeO}_4/x\text{Er}^{3+}$  shows various emission spectra by changing the concentration of  $\text{Er}^{3+}$  ions, as shown in Fig. 1. Both the intensities of the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT and  $\text{Er}^{3+}$  characteristic emission at 525 nm diminish while the highest intensity of  $\text{Er}^{3+}$  emission lines at 548 nm starts to increase and then diminishes by increasing the concentration of  $\text{Er}^{3+}$  ions,  $x$ , from 0.01 to 0.08. Among them, the highest emission intensity appears at  $x = 0.02$ . For  $x = 0.08$ , the main emission is the line peaks of  $\text{Er}^{3+}$  ions, and the broadband peak around 470 nm originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT is basically quenched. The results indicate that the energy transfer takes place from the triplet excited state of MLCT (metal-to-ligand charge transfer) state for  $\text{Sr}_2\text{CeO}_4$  (sensitizer) to  $\text{Er}^{3+}$  ions [9].

In the spectra, the characteristic emission band of  $\text{Er}^{3+}$  ions is quite narrow and the intensity is very low. This is because the electron configuration of  $\text{Er}^{3+}$  ions is  $4f^{11}$  and the ground state is  ${}^4\text{I}_{15/2}$ . The core-polarization and orbital crossing in  $5s^25p^6$  electron shell cause the energy of unsaturated  $4f$  electron to be higher than that of  $5s^25p^6$ . Moreover, the orbital radius of  $5s^25p^6$  electrons (0.176 nm) is wider than that of  $4f$  (0.100 nm). Consequently, the  $4f$  electrons are effectively shielded by the  $5s^25p^6$  electron shell. The f-f transition is the transition of  $4f$  electrons within the shell which makes the electron-phonon coupling between the rare earth ions and the crystal lattice very weak, even far lower than the spin-orbit interaction. The effect of the host crystal field on the  $4f$  electrons shows a magnitude at about  $10^1\text{-}10^2$   $\text{cm}^{-1}$ , and thus the characteristic emission of  $\text{Er}^{3+}$  ions is very narrow in band width and the intensity is very low [10].

Figure 2 shows the excitation spectra of  $\text{Sr}_2\text{CeO}_4/0.02\text{Er}^{3+}$  when excited with  $\lambda = 468$  and 548 nm respectively. As shown in Fig. 2, a broadband peak originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT is observed in both excitation spectra 1 and 2, in which the highest peak appears at 283 nm and a shoulder peak is observed at 336 nm. In addition, weak peaks are observed at 379 and 489 nm when excited with  $\lambda = 548$  nm, which correspond to the  ${}^4\text{I}_{15/2} \rightarrow {}^4\text{G}_{11/2}$  and  ${}^4\text{I}_{15/2} \rightarrow {}^4\text{F}_{7/2}$  t transitions of  $\text{Er}^{3+}$  ions [11] respectively. Because  $\text{Er}^{3+}$  ions show the  ${}^4\text{S}_{3/2} \rightarrow {}^4\text{I}_{15/2}$  characteristic transition with  $\lambda = 548$  nm, the

**Fig. 2** Emission spectra of  $\text{Sr}_2\text{CeO}_4: 0.02\text{Er}^{3+}$   
1.  $\lambda_{\text{em}} = 468$  nm; 2.  $\lambda_{\text{em}} = 548$  nm

luminescence of  $\text{Er}^{3+}$  ions is mainly attributed to the energy transfer from the triplet excited state of the MLCT state to the intra-4f excited state of  $\text{Er}^{3+}$  ions through  $\text{Ce}^{4+}\text{-O}^{2-}$  [9].

Figure 3 shows the emission spectra of  $\text{Sr}_2\text{CeO}_4/x\text{Er}^{3+}$  when excited with  $\lambda = 658$  nm. As shown in Fig. 3, two obvious peaks appear at 525 and 548 nm, which are assigned to the green up-conversion luminescence of the  ${}^2\text{H}_{11/2} \rightarrow {}^4\text{I}_{15/2}$  and  ${}^4\text{S}_{3/2} \rightarrow {}^4\text{I}_{15/2}$  transitions respectively. And when  $\text{Er}^{3+}$  ions are doped at 4%, the green up-conversion luminescence is the best [1,14].

**Fig. 3** Emission spectra of  $\text{Sr}_2\text{CeO}_4:x\text{Er}^{3+}$  ( $\lambda_{\text{ex}} = 658$  nm)  
1.  $x = 0.01$ ; 2.  $x = 0.02$ ; 3.  $x = 0.04$ ; 4.  $x = 0.08$

### 3.2 Luminescent properties of $\text{Sr}_2\text{CeO}_4/\text{Ho}^{3+}$

Figure 4 shows the emission spectra of  $\text{Sr}_2\text{CeO}_4/x\text{Ho}^{3+}$  when excited with  $\lambda = 283$  nm. As shown in Fig. 4, the emission spectra of  $\text{Sr}_2\text{CeO}_4/x\text{Ho}^{3+}$  are composed of broadband peaks and line peaks. A broadband peak around 470 nm appears between 400 and 540 nm originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT. A number of line emission peaks are attached to the broadband peak originating from the  $4f \rightarrow 4f$  excited state of  $\text{Ho}^{3+}$ , which are assigned to the  ${}^5\text{F}_3 \rightarrow {}^5\text{I}_8$  (491 nm),  ${}^5\text{S}_2 \rightarrow {}^5\text{I}_8$  (542, 549 nm) and  ${}^5\text{G}_6, {}^5\text{F}_1 \rightarrow {}^5\text{I}_7$  (614 nm) transitions [12,15–17], respectively. Among them, the strongest peak appears at 549 nm.

**Fig. 4** Emission spectra of  $\text{Sr}_2\text{CeO}_4:x\text{Ho}^{3+}$  ( $\lambda_{\text{ex}} = 283$  nm)  
1.  $x = 0.01$ ; 2.  $x = 0.02$ ; 3.  $x = 0.05$ ; 4.  $x = 0.08$ ; 5.  $x = 0.10$

$\text{Sr}_2\text{CeO}_4/x\text{Ho}^{3+}$  shows various emission spectra by changing the concentration of  $\text{Ho}^{3+}$  ions, as shown in Fig. 4. Both the emission intensities of the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT and the

${}^5\text{F}_3 \rightarrow {}^5\text{I}_8$  (491 nm),  ${}^5\text{S}_2 \rightarrow {}^5\text{I}_8$  (542, 549 nm) characteristic transitions of  $\text{Ho}^{3+}$  ions are gradually diminished by increasing the concentration of  $\text{Ho}^{3+}$  ions while that of  ${}^5\text{G}_6, {}^5\text{F}_1 \rightarrow {}^5\text{I}_7$  (614 nm) transition almost does not change. For  $x \geq 0.05$ , the main emission is the line peaks of  $\text{Ho}^{3+}$  ions, and the broadband peak around 470 nm originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT is very weak. The results indicate that the energy transfer takes place from the triplet excited state of MLCT (metal-to-ligand charge transfer) state for  $\text{Sr}_2\text{CeO}_4$  (sensitizer) to  $\text{Ho}^{3+}$  ions [9].

When  $x$  changes from 0.01 to 0.10, the strongest emission peak of  $\text{Ho}^{3+}$  around 549 nm is gradually diminished, and the highest peak is at  $x = 0.01$ . It is likely that the distance diminishes and the interaction increases continuously between  $\text{Ho}^{3+}$  ions by increasing the concentration of  $\text{Ho}^{3+}$  ions. Thus, it is inevitable that the energy transfer of some non-radiative transitions between  $\text{Ho}^{3+}$  ions occurs. Besides the multiphonon decay, the life of the emission energy state is also decreased due to the process of the cross-relaxation between  $\text{Ho}^{3+}$  ions with the same properties, so the luminescence intensity diminishes [17].

Figure 5 shows the excitation spectra of  $\text{Sr}_2\text{CeO}_4/0.01\text{Ho}^{3+}$  when excited with  $\lambda = 468$  and 549 nm, respectively. As shown in Fig. 5, a broadband peak originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT is observed in both excitation spectra 1 and 2, in which the highest peak appears at 283 nm and a shoulder peak is observed at 336 nm. In addition, a weak line peak is observed at 421 nm when excited with  $\lambda = 549$  nm, corresponding to the  ${}^5\text{I}_8 \rightarrow {}^5\text{G}_5$  transition of  $\text{Ho}^{3+}$  ions [16]. Because  $\text{Ho}^{3+}$  ions show the  ${}^5\text{S}_2 \rightarrow {}^5\text{I}_8$  characteristic transition with  $\lambda = 549$  nm, the luminescence of  $\text{Ho}^{3+}$  ions is mainly attributed to the energy transfer from the triplet excited state of the MLCT state to the intra 4f excited state of  $\text{Ho}^{3+}$  ions through  $\text{Ce}^{4+}\text{-O}^{2-}$  [9].

**Fig. 5** Excitation spectra of  $\text{Sr}_2\text{CeO}_4:0.01\text{Ho}^{3+}$   
1.  $\lambda_{\text{em}} = 468$  nm; 2.  $\lambda_{\text{em}} = 549$  nm

Figure 6 shows the emission spectra of  $\text{Sr}_2\text{CeO}_4/x\text{Ho}^{3+}$  when excited with  $\lambda = 880$  nm. As shown in Fig. 6, three obvious peaks appear at 481, 550 and 587 nm, which are assigned to the blue up-conversion luminescence of the  ${}^5\text{F}_3 \rightarrow {}^5\text{I}_8$  transition, green of the  ${}^5\text{S}_2 \rightarrow {}^5\text{I}_8$  transition, and

**Fig. 6** Emission spectra of  $\text{Sr}_2\text{CeO}_4:\text{xHo}^{3+}$  ( $\lambda_{\text{ex}} = 880$  nm)  
1.  $x = 0.01$ ; 2.  $x = 0.05$ ; 3.  $x = 0.10$

yellow of the  ${}^5\text{G}_4 \rightarrow {}^5\text{I}_6$  transition [18,19], respectively. And when  $\text{Ho}^{3+}$  ions are doped at 1%, the results are the best. Also as shown in Fig. 6, the up-conversion fluorescence is a broadband emission around 550 nm between 540 and 557 nm. This emission energy corresponds to the transition from the  ${}^5\text{S}_2$  state to the ground state  ${}^5\text{I}_8$  or it may be caused by the transition from the  ${}^5\text{F}_4$ ,  ${}^5\text{S}_2 \rightarrow {}^5\text{I}_8$ , since the energies of  ${}^5\text{S}_2$  and  ${}^5\text{F}_4$  are close to each other [20,21]. However, the up-conversion fluorescence mechanism of  $\text{Ho}^{3+}$  ions is a step absorption of up-conversion in a single ion. Therefore, the up-conversion broadband of fluorescence emission from 540 to 557 nm, corresponding to the  ${}^5\text{S}_2 \rightarrow {}^5\text{I}_8$  transition, is observed when excited with  $\lambda = 880$  nm. In addition, the ground state  ${}^3\text{I}_8$  splits into 17 levels in theory, so the band of fluorescence emission is very wide [19].

### 3.3 Luminescent properties of $\text{Sr}_2\text{CeO}_4/\text{Tm}^{3+}$

Figure 7 shows the emission spectra of  $\text{Sr}_2\text{CeO}_4/\text{xTm}^{3+}$  when excited with  $\lambda = 283$  nm. As shown in Fig. 7, the emission spectra of  $\text{Sr}_2\text{CeO}_4/\text{xTm}^{3+}$  are composed of broadband peaks and line peaks. A broadband peak around 470 nm appears between 400 and 540 nm originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT. A number of line emission peaks are attached to the broadband peak originating from the  $4f \rightarrow 4f$  excited state of  $\text{Tm}^{3+}$ , which are assigned to the  ${}^1\text{G}_4 \rightarrow {}^3\text{H}_6$  (476 nm) and  ${}^1\text{D}_2 \rightarrow {}^3\text{H}_5$  (544 nm) transitions, respectively [9,12]. Among them,

**Fig. 7** Emission spectra of  $\text{Sr}_2\text{CeO}_4:\text{Tm}^{3+}$  ( $\lambda_{\text{ex}} = 283$  nm)  
1.  $x = 0.01$ ; 2.  $x = 0.02$ ; 3.  $x = 0.05$ ; 4.  $x = 0.08$ ; 5.  $x = 0.10$

the strongest peak appears at 476 nm. In addition, a splitting occurs at the emission peaks of  $\text{Tm}^{3+}$  ions from the  ${}^1\text{G}_4 \rightarrow {}^3\text{H}_6$  (476 nm) and  ${}^1\text{D}_2 \rightarrow {}^3\text{H}_5$  (544 nm) transitions due to the crystal field interaction. And the splitting extents of emission peaks are determined by the symmetry of the crystal field around the host material.  $\text{Sr}_2\text{CeO}_4/\text{xTm}^{3+}$  shows various emission spectra by changing the concentration of  $\text{Tm}^{3+}$  ions, as shown in Fig. 7. Both the emission intensities of the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT and the  ${}^1\text{G}_4 \rightarrow {}^3\text{H}_6$  (476 nm) transition of  $\text{Tm}^{3+}$  ions are gradually decreased by increasing the concentration of  $\text{Tm}^{3+}$  ions, but the emission peak of the  ${}^1\text{D}_2 \rightarrow {}^3\text{H}_5$  (544 nm) transition no longer occurs with  $x \geq 0.02$ . For  $x \geq 0.05$ , the main emission is the line peaks of  $\text{Tm}^{3+}$  ions, and the broadband peak around 470 nm originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT is basically quenched. The results indicate that the energy transfer takes place from the triplet excited state of MLCT (metal-to-ligand charge transfer) state for  $\text{Sr}_2\text{CeO}_4$  (sensitizer) to  $\text{Tm}^{3+}$  ions [9].

Figure 8 shows the excitation spectra of  $\text{Sr}_2\text{CeO}_4/0.01\text{Tm}^{3+}$  and  $\text{Sr}_2\text{CeO}_4/0.05\text{Tm}^{3+}$  when excited with  $\lambda = 476$  nm. As shown in Fig. 8, a broadband peak originating from the  $\text{Ce}^{4+}\text{-O}^{2-}$  MLCT is observed in both excitation spectra 1 and 2. Because  $\text{Tm}^{3+}$  ions show the  ${}^1\text{G}_4 \rightarrow {}^3\text{H}_6$  characteristic transition with  $\lambda = 476$  nm, the luminescence of  $\text{Tm}^{3+}$  ions is mainly attributed to the energy transfer from the triplet excited state of the MLCT state to the intra 4f excited state of  $\text{Tm}^{3+}$  ions through  $\text{Ce}^{4+}\text{-O}^{2-}$  [9].

**Fig. 8** Excitation spectra of ( $\lambda_{\text{em}} = 476$  nm)  
1.  $\text{Sr}_2\text{CeO}_4:0.01 \text{Tm}^{3+}$ ; 2.  $\text{Sr}_2\text{CeO}_4:0.05 \text{Tm}^{3+}$

Figure 9 shows the emission spectra of  $\text{Sr}_2\text{CeO}_4/\text{xTm}^{3+}$  when excited with  $\lambda = 650$  nm. As shown in Fig. 9, the blue up-conversion luminescence appears at 476 nm, which is

**Fig. 9** Emission spectra of  $\text{Sr}_2\text{CeO}_4:\text{xTm}^{3+}$  ( $\lambda_{\text{ex}} = 650$  nm)  
1.  $x = 0.01$ ; 2.  $x = 0.02$ ; 3.  $x = 0.05$ ; 4.  $x = 0.08$ ; 5.  $x = 0.10$

assigned to the  ${}^1G_4 \rightarrow {}^3H_6$  transition. And when the doping amount of  $Tm^{3+}$  ions is 1%, the blue up-conversion luminescence is the best [14,22]. In addition, a group of weak broadband emissions appears at 544 nm, which are assigned to the  ${}^1D_2 \rightarrow {}^3H_5$  transition [12].

## 4 Conclusions

(1)  $Sr_2CeO_4/Ln^{3+}$  ( $Ln = Er, Ho, Tm$ ) phosphors are synthesized by the microwave irradiation method for the first time. Compared with the methods in literature, our method shows that the heating time is shortened to 60 min, easy to operate and no need for a high calcinating temperature.

(2)  $Sr_2CeO_4/Ln^{3+}$  ( $Ln = Er, Ho, Tm$ ) shows various fluorescence spectra by changing the concentration of  $Ln^{3+}$  ions. The spectra indicate that the energy transfer takes place from the triplet excited state of MLCT (metal-to-ligand charge transfer) state for  $Sr_2CeO_4$  (sensitizer) to the rare earth ions (activator).

(3) The spectra of  $Sr_2CeO_4/Er^{3+}$  show that the green up-conversion luminescence of  $Er^{3+}$  ions appear at 525 and 548 nm when excited with  $\lambda = 658$  nm. And when  $Er^{3+}$  ions are doped at 4%, the green up-conversion luminescence is the best. The spectra of  $Sr_2CeO_4/Ho^{3+}$  show that a blue up-conversion luminescence of  $Ho^{3+}$  ions appears at 525 nm, green at 550 nm and yellow at 548 nm, respectively, when excited with  $\lambda = 880$  nm. And when  $Ho^{3+}$  ions are doped at 1%, the green up-conversion luminescence is the best. The spectra of  $Sr_2CeO_4/Tm^{3+}$  show that a blue up-conversion luminescence of  $Tm^{3+}$  ions appears at 476 nm when excited with  $\lambda = 650$  nm. And when  $Tm^{3+}$  ions are doped at 1%, the blue up-conversion luminescence is the best.
