ABSTRACT   Over the past several decades, a variety of technical ways have been developed in seismic retrofitting of existing reinforced concrete frames (RFs). Among them, pin-supported rocking walls (PWs) have received much attentions to researchers recently. However, it is still a challenge that how to determine the stiffness demand of PWs and assign the value of the drift concentration factor (*DCF*) for entire systems rationally and efficiently. In this paper, a design method has been exploited for seismic retrofitting of existing RFs using PWs (RF-PWs) via a multi-objective evolutionary algorithm. Then, the method has been investigated and verified through a practical project. Finally, a parametric analysis was executed to exhibit the strengths and working mechanism of the multi-objective design method. To sum up, the findings of this investigation show that the method furnished in this paper is feasible, functional and can provide adequate information for determining the stiffness demand and the value of the *DCF* for PWs. Furthermore, it can be applied for the preliminary design of these kinds of structures.

KEYWORDS   pin-supported rocking wall, reinforced concrete frame, seismic retrofit, stiffness demand, drift concentration factor, multi-objective design, genetic algorithm, Pareto optimal solution

1   Introduction

In the last few decades, reinforced concrete frames (RFs) have been utilized widely in seismic areas all over the world. It is well-known that an RF should possess enough energy dissipation capacity and ductility in order to reduce seismic responses [1,2]. Consequently, it often causes large residual drifts and momentous structural damage under severe seismic excitations. On account of this, severe economic losses will be incurred and rebuilding or repairing necessities will be needed after a serious earthquake. Furthermore, the idea of "Strong Column Weak Beam" has been adopted in leading seismic design codes in many countries for several decades [3]. However, weak-story failures and inter-story drift concentrations have emerged in some high-rise frames designed on the basis of the existing codes. Besides, many existing RFs have structural deficiencies owing to the inadequacy of old design provisions, e.g., some regions with high seismic risks now were not diagnosed as they are or their levels of seismic hazards were underestimated before the upgraded codes [4].

In the light of the reasons depicted above, the seismic retrofitting of existing RFs is considered to be increasingly drawing the attention in earthquake engineering field currently. Numerous techniques have been

developed for seismic retrofitting of existing RFs and can be employed in combination or alternatively to improve the seismic performance of structures, such as: Buckling Restrained Braces (BRBs) [5–9], Fiber-Reinforced Polymer (FRP) [4,10], Base Isolation [11–17], Precast concrete spreader-wall [18], Dissipative steel exoskeletons [19] and reinforced concrete rocking walls [1,20–24], etc.

Among them, RC rocking walls have been exploited to mitigate the seismic vulnerability of existing structures in the last decade [21,25]. Generally speaking, reinforced concrete rocking walls can be classified into two categories, viz. pin-supported and stepping rocking walls (see Fig. 1). Their major difference is that the former rocks around only one fulcrum, while the latter has fulcrums on both sides of the bottom of the rocking wall [26]. In this paper, the pin-supported rocking walls (PWs) is concentrated on and investigated both conceptually and theoretically.

Moreover, the existing body of research on retrofitting of existing RFs via PWs suggests that the deformation pattern of RFs can be controlled effectively using PWs so as to avoid weak story failures and inter-story drift concentrations [1,27]. The effectiveness of PWs in reducing inter-story drift concentrations can be indicated viz. the drift concentration factor (DCF) [1,21], i.e., DCF can be employed to assess the uniformity of Inter-Drift Ratios (IDRs) of structures. The expression of DCF can be defined as Eq. (1).

$$DCF = \frac{\max_i \dfrac{d_i}{h_i}}{\Delta / \sum_i h_i},\tag{1}$$

where d_i, h_i, and Δ mean the inter-story displacement, the story height, and the roof displacement of structures, respectively. Specifically, the closer to 1.0 the value of DCF is, the better deformation pattern of the structure is controlled. However, a uniform DCF would be an ideal case while it would demand an impractical and infinite PW. Furthermore, a major problem in applying DCF to reflect PW's effect, which has been found in most previous research with regard to the stiffness demand, is difficult to assign a design target value, i.e., the determination of the DCF is blind and its physical meaning would be obscure. Therefore, it is worth studying that how to choose the appropriate DCF value in the light of the actual engineering requirements and structural performance demands.

In this study, a design method by a multi-objective evolutionary optimization (MEO) is explored for seismic retrofitting of existing RFs using PWs (RF-PWs). Specifically, based on genetic algorithm (GA) and the theories of RFs retrofitted with PWs, a group of Pareto Optimal Solutions (POSs) will be furnished, which not only meets the performance requirements of the retrofitted structures but also possesses a characteristic of diversity. Meantime, the physical meaning of DCFs and the performance of the retrofitted structures can be displayed clearly and intuitively. Afterwards, the best one can be selected by designers through comparing the differences of individuals in the POSs. The multi-objective design method may boost the preliminary design of this kind of structures.

2 Multi-objective evolutionary optimization via genetic algorithm

It is well-known that MEO methods have been the significant techniques to tackle practical problems in the last decade [28]. In engineering fields, most real-world problems get involved in optimizing multi-objectives simultaneously which have tradeoff relationship normally. In general, the commonly used form of the MEO problem can be stated as Eq. (2).

$$\left.\begin{aligned}\text{Minimize/maximize}\quad & F_m(z),\quad m=1,2,\ldots,M;\\ \text{subject to}\quad & G_j(z)\geqslant 0,\quad j=1,2,\ldots,J;\\ & H_k(z)=0,\quad k=1,2,\ldots,K;\\ & C_r(z)\leqslant 0,\quad r=1,2,\ldots,R;\\ & D_s(z)=0,\quad s=1,2,\ldots,S;\\ & z_{(l)i}\leqslant z_i\leqslant z_{(u)i},\quad i=1,2,\ldots,n.\end{aligned}\right\},\tag{2}$$

where z is the design variables' vector: $z = (z_1, z_2, \ldots, z_n)^T$; $F_m(z)$ is the objective functions' vector: $F_m(z) = (f_1(z), f_2(z), \ldots, f_M(z))^T$; $G_j(z)$ means the constraints' vector of linear inequality: $G_j(z) = (g_1(z), g_2(z), \ldots, g_J(z))^T$; $H_k(z)$ denotes the constraints' vector of linear equality: $H_k(z) = (h_1(z), h_2(z), \ldots, h_K(z))^T$; $C_r(z)$ stands for the constraints' vector of nonlinear inequality: $C_r(z) = (c_1(z), c_2(z), \ldots, c_R(z))^T$; $D_s(z)$ symbolizes the constraints' vector of nonlinear equality: $D_s(z) = (d_1(z), d_2(z), \ldots, d_S(z))^T$;

Fig. 1 Reinforced concrete rocking walls: (a) pin-supported rocking wall; (b) stepping rocking wall.

$z_{(l)i}$, $z_{(u)i}$ represent the lower and upper bounds on z_i, respectively.

In this study, GA was suggested to address this problem [29,30]. Meantime, the schematic of the EMO using GA is presented in Fig. 2.

Moreover, NSGA-II approach in which ranking is based sequentially on: (1) constraint satisfaction, (2) domination, and (3) crowding distance was utilized to address the multiobjective optimization [31,32]. The EMO using GA was executed through the GA Optimization Toolbox in Matlab [33]. Table 1 shows the parameters adopted by EMO using GA in this study.

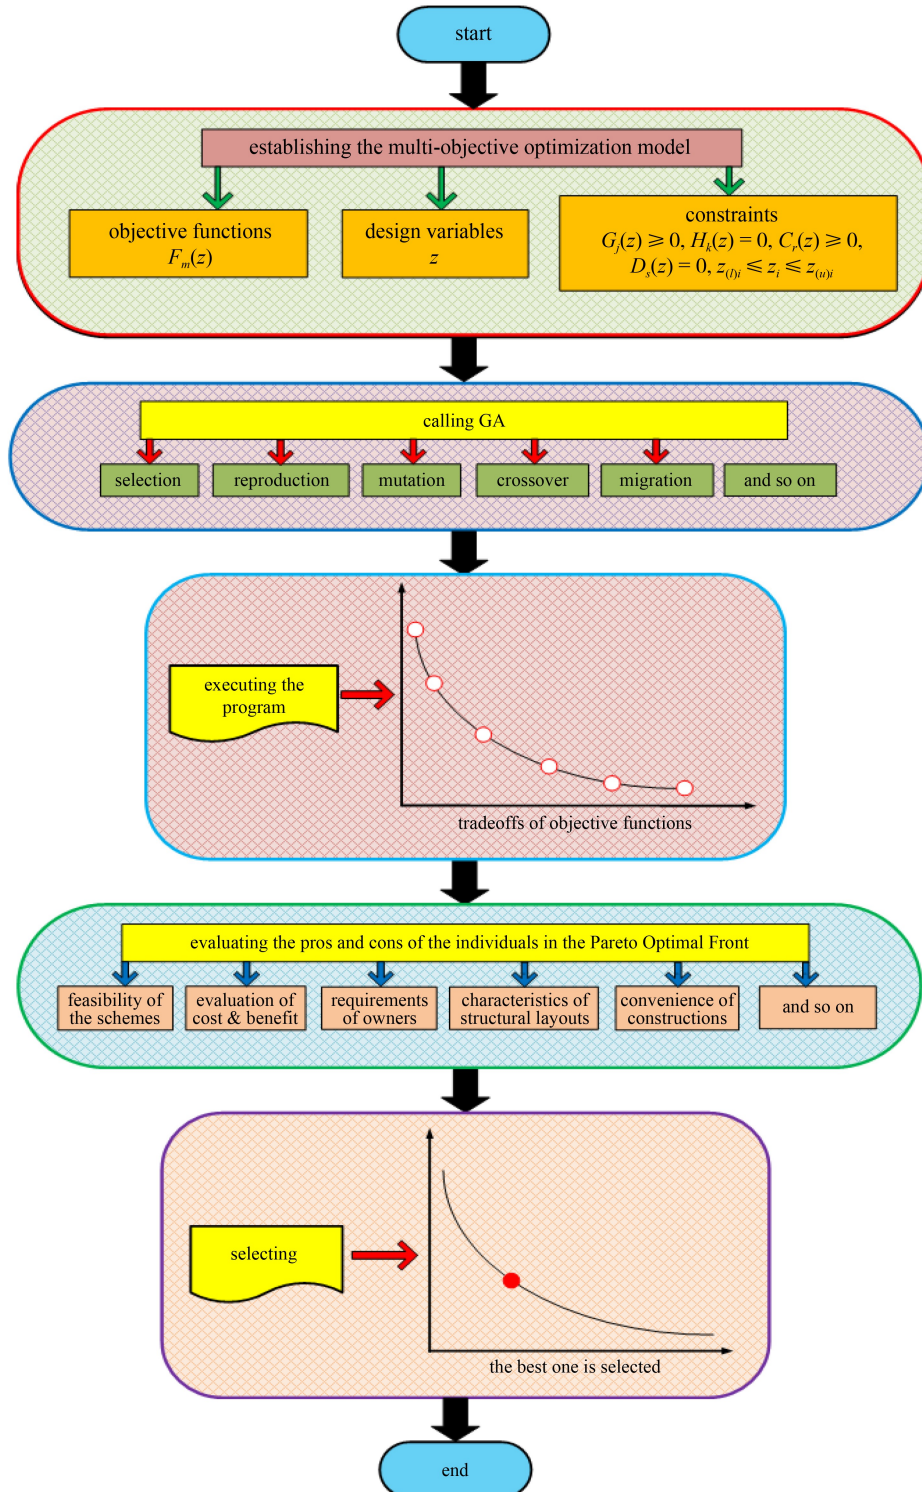

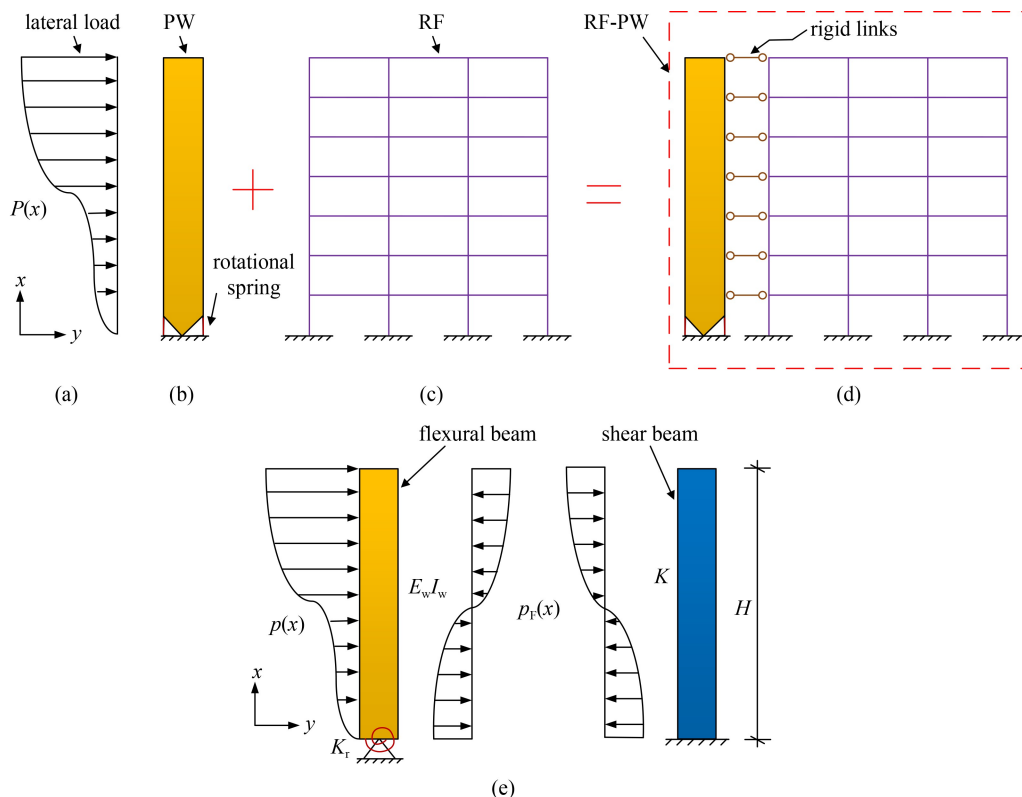

Fig. 2   Schematic of the EMO using GA.

Table 1 Parameters adopted by EMO using GA

parameter	value
type of population	double vector

fraction of Pareto front population	0.5
stopping criteria	50

3 Parametric model for seismic retrofitting of existing reinforced concrete frames using pin-supported rocking walls

In this study, the model for RF-PWs is displayed in Fig. 3. Figures 3(a)–3(e) represent the lateral load, RF, PW with a rotational spring, RF-PW and parametric model for RF-PWs, respectively. Specifically, the RF-PW is simulated as a combination of and one flexural beam one shear beam linked with rigid links at the location of the floors (see Fig. 3(e)). The flexural beam and the shear beam symbolize the PW and the RF, respectively.

In Fig. 3(e), $p(x)$ is the lateral load, which is assigned along the structure's height whereas $p_F(x)$ represents the distributed internal force between the RF and the PW, where x means the height from the bottom to a certain position of the structure; H stands for the entire structure's height; $E_w I_w$ is the bending stiffness of the PW; K with a unit of Newtons denotes the shear distributed stiffness of the RF, which equals the shear force when a unit IDR is applied. K_r is the rotational spring's stiffness on the bottom of the PW [26,34,35].

According to the Refs. [26,34], the differential equations and the corresponding solutions can be derived (see Tables 2 and 3) under four different lateral load models. Accordingly, the bending moment M_w and shear force V_w of the flexural beam can be obtained as Eqs. (3) and (4), respectively.

$$M_w = \frac{E_w I_w}{H^2} \frac{d^2 y}{d\xi^2}, \tag{3}$$

$$V_w = -\frac{E_w I_w}{H^3} \frac{d^3 y}{d\xi^3}. \tag{4}$$

4 Case study

4.1 Model of multi-objective evolutionary optimization via genetic algorithm

The problem of an RF-PW can be stated as follows:

Fig. 3 Model for RF-PWs: (a) lateral load; (b) PW with a rotational spring; (c) RF; (d) RF-PW; (e) parametric model of RF-PWs.

Table 2   Expressions of $y(\xi)$ corresponding to the four different $p(\xi)$

$p(\xi)$	differential equations	solutions of differential equations	boundary conditions
q	$-\lambda^2\dfrac{d^2 y}{d\xi^2} = \dfrac{qH^4}{E_w I_w}$	$y(\xi) = C_1 + C_2\xi + A\sinh\lambda\xi + B\cosh\lambda\xi - \dfrac{qH^2}{2K}\xi^2$	(1) When $x=H, (\xi=1)$, Shear blance, $\left(\dfrac{d^3 y}{d\xi^3} - \lambda^2\dfrac{dy}{d\xi}\right)_{\xi=1} = 0.$
$q\cdot\xi$	$-\lambda^2\dfrac{d^2 y}{d\xi^2} = \dfrac{q\xi H^4}{E_w I_w}$	$y(\xi) = C_1 + C_2\xi + A\sinh\lambda\xi + B\cosh\lambda\xi + \dfrac{qH^2}{6K}\xi^3$	(2) When $x=0, (\xi=0)$, Moment balance, $\left(R_f\dfrac{dy}{d\xi} - \dfrac{d^2 y}{d\xi^2}\right)_{\xi=0} = 0.$
$q\cdot\sqrt{\xi}$	$-\lambda^2\dfrac{d^2 y}{d\xi^2} = \dfrac{q\sqrt{\xi}H^4}{E_w I_w}$	$y(\xi) = C_1 + C_2\xi + A\sinh\lambda\xi + B\cosh\lambda\xi + \dfrac{4qH^2}{15K}\xi^{\frac{5}{2}}$	(3) When $x=0, (\xi=0)$, $y=0$, $y_{\xi=0}=0.$
F	$\dfrac{d^4 y}{d\xi^4} = \lambda^2\dfrac{d^2 y}{d\xi^2}$	$y(\xi) = C_1 + C_2\xi + A\sinh\lambda\xi + B\cosh\lambda\xi$	(4) When $x=H, (\xi=1)$, $\left(\dfrac{d^2 y}{d\xi^2}\right)_{\xi=1} = 0.$

Notes: $y(\xi)$ is the lateral displacement along the structure's height; $p(\xi)$ is the lateral load acting on the structure; ξ is the dimensionless height, $\xi = \dfrac{x}{H}$ and $0 \leqslant \xi \leqslant 1.0$; λ means the ratio of the stiffness between the shear beam and the flexural beam, $\lambda = H\sqrt{\dfrac{K}{E_w I_w}}$; R_f denotes the normalized rotational spring stiffness, $R_f = \dfrac{K_r H}{E_w I_w}$ and $0 \leqslant R_f < \infty$; C_1, C_2, A and B are the unknown coefficients of the solutions of the differential equations, respectively (see Table 3); F means a concentrated load at the top of the structure.

Table 3   Solutions of C_1, C_2, A and B

coefficients	uniformly distributed load	inverted triangular distributed load	parabolic distributed load	concentrated load at the top of the structure
φ	$\dfrac{1 - \cosh\lambda - R_f\cosh\lambda}{\sinh\lambda + \dfrac{R_f}{\lambda}\cosh\lambda}$	$\dfrac{1 - R_f\left(\dfrac{1}{2} - \dfrac{1}{\lambda^2}\right)\cosh\lambda}{\sinh\lambda + \dfrac{R_f}{\lambda}\cosh\lambda}$	$\dfrac{1 - R_f\left(\dfrac{2}{3} - \dfrac{1}{2\lambda^2}\right)\cosh\lambda}{\sinh\lambda + \dfrac{R_f}{\lambda}\cosh\lambda}$	$\dfrac{R_f\cosh\lambda}{\sinh\lambda + \dfrac{R_f}{\lambda}\cosh\lambda}$
C_1	$-\dfrac{qH^2}{K\lambda^2}\left(1 + R_f + \dfrac{R_f}{\lambda}\varphi\right)$	$-\dfrac{qH^2}{K\lambda^2}\left[\dfrac{R_f}{\lambda^2}\left(\dfrac{1}{2} - \dfrac{1}{\lambda^2}\right) + \dfrac{R_f}{\lambda}\varphi\right]$	$-\dfrac{qH^2}{K\lambda^2}\left[\dfrac{R_f}{\lambda^2}\left(\dfrac{2}{3} - \dfrac{1}{2\lambda^2}\right) + \dfrac{R_a}{\lambda}\varphi\right]$	$-\dfrac{FH}{K\lambda^2}\left(R_f - \dfrac{R_f}{\lambda}\varphi\right)$
C_2	$\dfrac{qH^2}{K}$	$\dfrac{qH^2}{K}\left(\dfrac{1}{2} - \dfrac{1}{\lambda^2}\right)$	$\dfrac{qH^2}{K}\left(\dfrac{2}{3} - \dfrac{1}{2\lambda^2}\right)$	$\dfrac{FH}{K}$
A	$\dfrac{qH^2}{K\lambda^2}\varphi$	$\dfrac{qH^2}{K\lambda^2}\varphi$	$\dfrac{qH^2}{K\lambda^2}\varphi$	$-\dfrac{FH^2}{K\lambda^2}\varphi$
B	$\dfrac{qH^2}{K\lambda^2}\left(1 + R_f + \dfrac{R_f}{\lambda}\varphi\right)$	$\dfrac{qH^2}{K\lambda^2}\left[\dfrac{R_f}{\lambda^2}\left(\dfrac{1}{2} - \dfrac{1}{\lambda^2}\right) + \dfrac{R_f}{\lambda}\varphi\right]$	$\dfrac{qH^2}{K\lambda^2}\left[\dfrac{R_f}{\lambda^2}\left(\dfrac{2}{3} - \dfrac{1}{2\lambda^2}\right) + \dfrac{R_f}{\lambda}\varphi\right]$	$\dfrac{FH}{K\lambda^2}\left(R_f - \dfrac{R_f}{\lambda}\varphi\right)$

Notes: φ is a symbol to simplify the expressions of C_1, A and B.

One Design Variable:

Find

$E_w I_w = E_w \cdot I_w$,

where $E_w I_w$ is the bending stiffness of the cross-section of the PW; E_w is the elasticity modulus of concrete of the PW; I_w means the section moment of inertia of the PW, $I_w = \dfrac{t_w b_w^3}{12}$; where t_w is the thickness of the PW (unit: m); b_w is the width of the PW (unit: m).

Two Trade-off Objective Functions:

(1) η and (2) DCF^{PW},

where $\eta = \dfrac{1}{\lambda}\cdot\eta$, the reciprocal of λ, is a nondimensional parameter representing the stiffness ratio between the flexural beam and shear beam; and DCF^{PW} is the DCF of the PW.

Constraints:

Subjected to:

(1) the range of the design variable, $E_w I_w$.

$$1.0\times 10^7 \leqslant E_w I_w \leqslant 1.0\times 10^9,$$

where in order to determine the range of the design variable, $t_w = 0.6$ and $1.0 \leqslant b_w < 9.0$ are assumed, respectively.

(2) the range of the maximum IDR of the RF-PW, IDR_{max}^{PW}.

$$0 < IDR_{max}^{PW} < IDR_{max}^{RF}.$$

For the efficiency of convergence of the optimization program, the restraint of IDR_{max}^{PW} is set between 0 and IDR_{max}^{RF}, where the IDR_{max}^{RF} denotes the maximum IDR of the RF and equals $1/1289$ in this case (see Table 5).

(3) the range of the DCF of the RF-PW, DCF^{PW}.

$$1.0 < DCF^{PW} < DCF^{RF},$$

where the DCF^{RF} denotes the DCF of the RF and equals 1.62 in this case.

4.2   Case employed in this study

Figure 4 presents an existing two-dimensional five-story RF [26]. In this case, the bending stiffness of the frame beams is assumed to be infinite; $K = 1.86\times 10^6$ kN; the uniformly distributed load is adopted as the lateral load acting on the structure, i.e., $p(\xi) = q$, where $q = 100$ kN/m; $K_r = 0$, i.e., no rotational spring is set. Furthermore, the

basic information of the RF is given in Table 4.

It is very easy to obtain the lateral displacement and *IDR*s of the RF by any kind of finite element software. The lateral displacements and IDR^{RF} of the RF are furnished in Table 5 and Fig. 5, respectively. As shown in Table 5 and Fig. 5, the maximum lateral displacement

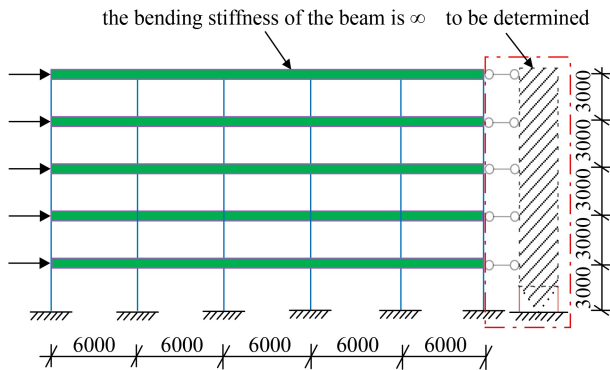

Fig. 4 Two-dimensional five-story RF before retrofitted.

Table 4 Material and geometrical dimensions of the RF

concrete	E_f (kN/m^2)	story number	story height (m)	span number	span (m)	columns' cross section (m^2)
C30	3.0×10^7	5	3.0	5	6.0	0.6×0.6

Note: E_f is the elasticity modulus of concrete for the RF.

Table 5 Lateral displacements and *IDR*s of the RF

position	lateral displacement (mm)	IDR^{RF}
roof	7.16577	1/5709
4th floor	6.64028	1/3045
3rd floor	5.65518	1/2083
2nd floor	4.21509	1/1588
1st floor	2.32695	1/1289
ground	0	–

Note: IDR^{RF} represents the *IDR* of the RF.

Fig. 5 (a) Lateral displacement and (b) *IDR* of the RF.

and IDR^{RF}_{max} of the structure are 7.17 mm and 1/1289, respectively. Furthermore, the DCF^{RF} of the structure equals 1.62 according to Eq. (1), where IDR^{RF}_{max} and DCF^{RF} represent the maximum *IDR* and the *DCF* of the RF, respectively.

5 Results analysis

According to Table 1, the number of POSs will be 50 in this case, for Population size and Pareto front population fraction are 100 and 0.5, respectively. Table 6 provides the 50 individuals of POSs at Generation 50. Figures 6 and 7 show the bar diagrams of two objective functions, viz. η and *DCF*, of 50 POSs at Generation 50, respectively. From Table 6 and Figs. 6–7, we can see that $0.169 \leqslant \eta \leqslant 1.514$, and $1.026 \leqslant DCF^{PW} \leqslant 1.494$. It is apparent that the values of DCF^{PW} are all smaller than the one of DCF^{RF}, viz. 1.62 (the red bar in right side of Fig. 7), which means the effectiveness of the PW in reducing inter-story drift concentrations of the RF.

Figure 8 displays the scatter diagram between two objective functions, viz. η and DCF^{PW}, at Generation 50. Looking at Fig. 8, it is clear that a trade-off correlation is demonstrated between η and DCF^{PW}, i.e., specifically, with the gradual increase of η, DCF^{PW} will continue to decrease, and vice versa. i.e., with the rise of $E_w I_w$, the deformation control effect of the PW on the RF will be increasingly obvious.

Figures 9 and 10 present the 3D and plan diagrams of the quantity distribution of objective function values of 50 POSs at Generation 50. From Figs. 9 and 10, we can see that some values of the objective functions among POSs are very close, which can be considered as equal individuals. e.g., when $1.45 \leqslant DCF^{PW} < 1.5$, $0.17 \leqslant \eta < 0.31$ and $1.03 \leqslant DCF^{PW} < 1.07$, $1.38 \leqslant \eta < 1.52$, there are 6 and 4 similar POSs, respectively. In addition, as shown in Figs. 9 and 10, there are 18 kinds of POSs, which displays a relatively uniform scatter. Also, no local convergence appears. As a consequence, the solutions of multi-objective optimization have the characteristic of diversity in contrast to the only one of single objective optimization.

Figures 11 and 12 display the scatter and bar diagrams of the distribution of the design variables, viz. the bending stiffness of the PW, $E_w I_w$, of 50 POSs at Generation 50, respectively. Figure 13 presents the diagram of the relationship between b_w and DCF^{PW}. From Figs. 11 and 12, we can see that the distribution of the design variables has good discreteness and diversity. From Fig. 13, it is evident that there is an inverse correlation between b_w and DCF^{PW}. Moreover, the width of the PW, viz. b_w can be acquired when t_w is set as 0.6 m and $E_w = E_f$, respectively (see Fig. 14). It can be seen from Table 6 and Fig. 14 that $2.0 \text{ m} \leqslant b_w \leqslant 8.6 \text{ m}$, which means there are a variety of options when designers try to

Notes: ζ is a nondimensional parameter, which represents the ratio between the maximum IDR of the RF-PW and the one of the RF, $\zeta = \dfrac{IDR_{max}^{PW}}{IDR_{max}^{RF}} \times 100\%$;

V_{wb} is the shear force at the bottom of the flexural beam; δ is a nondimensional parameter, which means the ratio between the shear force at the bottom of

the PW and the resultant force of the lateral load, $\delta = \dfrac{V_{wb}}{\int_0^1 p(\xi)\mathrm{d}\xi} \times 100\%$, e.g., if a uniformly distributed load, viz. $p(\xi) = q$, is employed, $\delta = \dfrac{V_{wb}}{q \cdot H} \times 100\%$.

Fig. 6 η of 50 POSs at Generation 50.

determine the value of b_w.

On the other hand, it is apparent that the distribution of individuals in POSs is also a little biased from Fig. 11. Specifically, more individuals cluster in the end with lower $E_w I_w$ value. In other words, there are more individuals with lower b_w and higher DCF^{PW} in terms of Fig. 14. The reason of this phenomenon may be linked with the constraints of the optimization problem, e.g., due to $1.0 \leqslant DCF^{PW} \leqslant 1.62$, the closer to the lower $E_w I_w$ value the individuals are (i.e., the DCF^{PW} nears to 1.0 and b_w approaches to 8.6 m), the less feasible the design schemes are. For as aforementioned, when the value of DCF closer to 1.0, the corresponding scheme will be impractical due to the demand of the infinite stiffness of the PW. In contrast, when $DCF^{PW} = 1.62$, the scheme corresponds to

Fig. 9 3D diagram of the quantity distribution of η and DCF^{PW} at Generation 50.

Fig. 13   Correlation between ζ and DCF^{PW} (when $t_w = 0.6$ m).

the RF, which is an existing structure, i.e., the RF-PW with a value of DCF close to 1.62, it needs a lower $E_w I_w$ and easy to be realized. From the perspective of probability, these kinds of solutions have a large probability of occurrence so as to cause the above-mentioned bias phenomenon.

λ has been utilized as a significant parameter in the previous studies on RF-PWs, which is the reciprocal of η as mentioned in Subsection 4.1. For the sake of comparison with the existing findings, the values and diagram of λ are provided in Table 6 and Fig. 15, respectively. As shown in Table 6 and Fig. 15, $0.66 \leqslant \lambda \leqslant 5.905$.

Figures 16 and 17 illustrate the bar diagrams of the distribution of IDR_{max}^{PW} and ζ of 50 POSs at Generation 50, respectively. Figure 18 provides the diagram of the relationship between η and ζ. From Table 6 and Fig. 16,

we can know that $\frac{1}{1978} \leqslant IDR_{max}^{PW} \leqslant \frac{1}{1359}$. It is clear that IDR_{max}^{PW} are all less than $IDR_{max}^{RF} = \frac{1}{1289}$ which reflects the effect of the RF after retrofitted by the PW. Furthermore, from Table 6 and Fig. 16, $0.652 \leqslant \zeta \leqslant 0.948$, which means the ratios of IDR_{max}^{PW} over IDR_{max}^{RF} are from 65.2% to 94.8%, respectively.

Moreover, from Fig. 18, it is apparent that the correlation between η and ζ is inverse. That is to say, with the increase of the $E_w I_w$, the lateral global stiffness of the RF-PW increasingly ascends, so as to lead to the decrease of the IDR_{max}^{PW}.

Figure 19 presents the correlation between ζ and IDR_{max}^{PW}. From Fig. 19, it is apparent that ζ is linearly and positively proportional to IDR_{max}^{PW}, i.e., the larger ζ of the structure is, the bigger the corresponding IDR_{max}^{PW} is, and vice versa. In addition, the values of ζ and IDR_{max}^{PW} are distributed in a reasonable scope, which meets the optimization constraints, such as: $0 < IDR_{max}^{PW} < \frac{1}{1289}$ and $1.0 \leqslant DCF_{max}^{PW} \leqslant 1.62$.

Figures 20 and 21 demonstrate the bar diagrams of the distribution of V_{wb} and δ of 50 POSs at Generation 50, respectively. Figure 22 presents the diagram of the relationship between η and δ. From Table 6 and Fig. 20, we can know that 252.4 kN $\leqslant V_{wb} \leqslant 723.2$ kN, which means the PW shares the lateral load with the RF. Also, From Table 6 and Fig. 21, the ratios of V_{wb} over the resultant force of the lateral load $q \cdot H$, viz. δ are from 15.2% to 43.4%, respectively, which reveals the efficiency provided by the PW to the RF. Furthermore, according to Fig. 22, it is clear that with the increase of η, δ ascends gradually, and vice versa. Meanwhile, when $\eta \leqslant 0.4$, there is an approximately linear relationship
**Fig. 14**   Bar diagram of the distribution of b_w at Generation 50 (when $t_w = 0.6$ m).

Fig. 15   Bar diagram of the distribution of λ at Generation 50.

between them. By contrast, when $\eta > 0.4$, the growth rate of δ begins to decline gradually and inclines to zero finally, which shows the maximum V_{wb} shared by the PW will not exceed 45% of the resultant force of the lateral load $q \cdot H$ in this case.

Lastly, returning to the aim posed at the beginning of this paper, it is now possible to demonstrate how to apply this multi-objective design method. For instance, (1) if designers want to determine the scheme with the minimum IDR_{max}^{PW}, individual No. 3 would be the best choice on the basis of Table 6. Meantime, other performance indexes relating to individual No. 3 can be found in Table 6 as well; (2) Assuming according to the

characteristics of structural plane layout, $b_w = 4.0$ m is suitable to it. As a result, individual No. 21 can be chosen as the best one in the light of Table 6; (3) if a design target value of DCF^{PW} is assigned as 1.320, individual No. 42 would be the second-one choice. The corresponding performance indexes of the 3 chosen individuals can be found in Table 7.

6   Conclusions

The following conclusions can be drawn from the present study.

1) A multi-objective design method has been developed for seismic retrofitting of existing RFs using PWs. Then, it has been investigated and verified via a real structure. The results demonstrated that this method is feasible, practical and can be employed for the preliminary design of these kinds of structures.

2) MEO is integrated to produce POSs with a certain number of structural performance indexes. After that, the most suitable one can be picked out based on the requirements of practical projects so that the blindness in determining the target value of *DCF* can be addressed.

3) Owing to POSs, designers can compare and weigh the pros and cons of them, a best one can be determined so that the idea of performance-based design can be realized through this method.

Limitation and future studies:

Table 7 Performance indexes of the 3 chosen individuals

No.	η	DCF^{PW}	$E_{\mathrm{w}}I_{\mathrm{w}}\times10^{-7}$ (kN·m²)	b_{w} (m) $t_{\mathrm{w}}=0.6$ m	λ	$IDR_{\max}^{\mathrm{PW}}$	ζ	V_{wb} (kN)	δ
3	1.514	1.026	96.0	8.6	0.660	1/1978	65.2%	723.2	43.4%
21	0.484	1.189	9.812	4.0	2.065	1/1708	75.5%	562.3	33.8%

1) In this paper, the research about the proposed design procedure of PWs as retrofitting system is based on elastic theory. The nonlinear seismic analysis are necessary to investigate the actual behavior of the RF-PWs.

2) The effects of the high modes are getting obvious with the increase of structure height. Therefore, the effects of the high modes should be considered when analyzing the structural performance.
