Motivation

- Mobile P2P (MP2P) networks do not have central administration and peers are autonomous; the peers are inherently insecure and untrustworthy. Thus, it is very challenging to construct a trust relationship between two peers in an MP2P network.
- Group-based trust models have drawn increasing attention from experts in various types of fields.
- In the existing group-based trust models, the members in a group are fixed once the grouping is completed, which is not appropriate for MP2P networks.

Main idea

- It is noted that peers with the same or similar interests are more capable of maintaining cooperation. This characteristic can help guarantee the stability of the trust relationship between peers.
- The proposed model can guarantee a stable successful transaction rate in MP2P networks.

Method

- Introduce three roles of peers and the concept of similarity that peers are dynamically divided into groups based on their interests.
- Present a trust management model based on two new trust metrics: intragroup trust and intergroup trust.
- Carry out various experiments based on the proposed framework.

Major results (I)

- Compared with SGTM, M-Trust, and PowerTrust, our model can generate more steady successful transaction rates.

Fig. 2 The successful transaction rate with peers joining (a), peers leaving (b), and movement velocity (c)

Major results (II)

- Compared with SGTM, M-Trust, and PowerTrust, our method generates less communication overhead.

Fig. 3 Number of messages vs. the number of peers (a) and movement velocity (b)

Conclusions

- Inspired by the observations in a recent survey, this paper presents a novel model, the dynamic grouping based trust model.
- We proposed two trust metrics, intragroup trust and intergroup trust, which can be used to accurately measure the trust between peers in MP2P networks.
- We demonstrated the performance of our model through a series of simulations.
