

## Supplement of Figures and Table

### A. Total $\alpha$ -syn AlphaLISA assay

### B. Oligomer $\alpha$ -syn AlphaLISA assay

Figure S1 Schematic illustration of AlphaLISA assays for total and oligomeric  $\alpha$ -syn models. (A) Total  $\alpha$ -syn AlphaLISA assay: acceptor-beads (red) were conjugated to the Life antibody (targeting a.a. 121-125 of  $\alpha$ -syn), whereas the Nb antibody was biotinylated and conjugated with the streptavidin-coated donor beads (blue). (B) Oligomer  $\alpha$ -syn AlphaLISA assay, Life antibody coupled with Acceptor beads will not detect monomers due to occupancy of the same epitope by the biotinylated Life antibody. Only the oligomeric form of  $\alpha$ -syn can provide multiple epitopes for binding of both the acceptor beads-conjugated and the donor beads-conjugated Life antibodies, so that AlphaLISA signals could be generated.

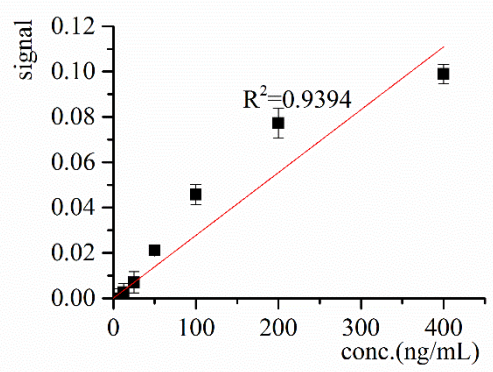

Figure S2 Development of AlphaLISA assays for detection of oligomeric and total  $\alpha$ -syn. (A) TR-FRET assay of the purified protein in Fig.1A use the Life /Life antibody pair. The protein was tested at different concentrations indicated in the X-axis and the signals were fitted with  $Y=kX$ .  $R^2$  indicates the regression parameter. (B) Similar as A, but use the Life/Nb antibody pair. (C) Coomassie staining (blue) and western blot detection of indicated SEC-fractionated samples on NativePAGE, using the Life antibody. (D) Similar as C, but uses A53T protein. (E) The Life/Life antibody pair TR-FRET detection of the indicated  $\alpha$ -syn protein samples from SEC at  $1\mu\text{g/mL}$  on 384-well microtiter plates ( $n=3$ ). The monomeric samples a12 & a16, A12 & A16 generated much smaller signals compared to oligomeric samples a10 and A10. (F) Similar as E, but use the Life/Nb antibody pair. All samples gave signals. (G) The ratio between Life/Life signals and the Life/Nb signals was calculated for the TR-FRET assay, and this ratio (O/T) separates oligomeric and monomeric samples. For E-G, plots indicate mean  $\pm$ S. E, and  $n=3$ .

A. TR-FRET assay with Life/Life

B. TR-FRET assay with Life/Nb

C. AlphaLISA assay with Life/Life

D. AlphaLISA assay with Life/Nb

Figure S3 AlphaLISA has a higher sensitivity than TR-FRET and can detect lower concentration of  $\alpha$ -syn. (A) TR-FRET assay of the purified protein in Fig.1A use the Life /Life antibody pair. The protein was tested at different concentrations indicated in the X-axis and the signals were fitted with  $Y=kX$ .  $R^2$  indicates the regression parameter.

(B) Similar as A, but use the Life/Nb antibody pair. (C) Similar as A, but testing with the AlphaLISA assay using the Life/Life antibody pair. (D) Similar as C, but using the Life/Nb antibody pair. For A-D, plots indicate mean  $\pm$ S. E, and  $n=3$ .

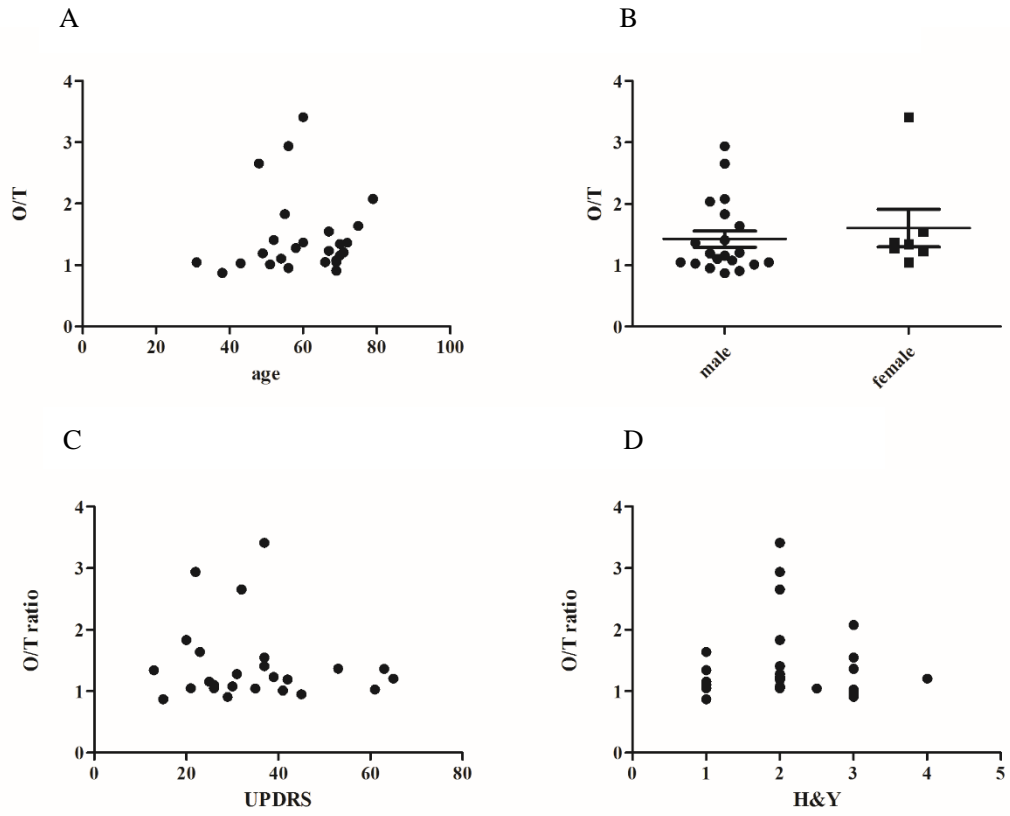

Figure S4 The correlation of the CSF O/T ratio with age, gender, H&Y value and UPDRS score within the PD cohort. (A) Age. (B) gender. (C) UPDRS. (D) H&Y. There has no correlation with these factors.

**Table S1 Demographics, clinical features and biomarkers value**

	PD ( n=26 )	MSA ( n=20 )	Control ( n=28 )	P value
Age(years)	59.8 ( 11.9 )	57.4 ( 6.8 )	61.2 ( 10.9 )	0.293
Gende(M/F)	19/7	11/9	19/9	0.426
Disease duration(month)	56.6 ( 43.2 )	29.0 ( 22.0 )	NA	
H&Y stage	2.2 ( 0.8 )	3.6 ( 0.7 )	NA	
UPDRS-III off score	34.7 ( 14.2 )	36.5 ( 14.7 )	NA	
Oligomer $\alpha$ -syn	187.0 ( 74.9 )	158.5 ( 49.1 )	153.3 ( 28.2 )	0.477
Total $\alpha$ -syn	132.8 ( 31.5 )	125.1 ( 25.8 )	150.5 ( 39.3 )	0.021*
O/T ratio	1.45 ( 0.65 )	1.31 ( 0.52 )	1.06 ( 0.25 )	0.026*

M=male, F=female, UPDRS = Unified Parkinson's Disease Rating Scale, H&Y= Hoehn and Yahr stage; Data are shown as mean (SD)
